Capturing behaviour of sustainability managers through vial

< ∃ >

### My aim

My aim is to convince you that viability theory provides a mathematical framework to model and solve many economic problems that is more general than *e.g.* optimisation or stability analysis.

- In particular, sustainability problems are naturally amenable to viability analysis.
- I will show you how some specific questions concerning a by-catch fishery are answered using viability theory.
- Managers' behaviour whose concern is prioritisation of solutions proposed by experts can be easily captured by viability analysis.
- Viability analysis can be more robust than optimisation or stability analysis.

- Given a dynamic system with state constraints, V is the set of all state-space points, from which it is possible to to start an evolution that remains within the constraints indefinitely. V the viability kernel - the principal analytical tool of viability analysis.
- Viability kernels are usually determined numerically.
- Algorithms and specialised software called vikaasa to compute  $\mathcal{V}$ , will be described here and
- applied to solve a by-catch fishery problem.

## Viability $\approx$ Sustainability

Sustainability problems arise in situations where human interaction with a dynamic, changing environment can potentially lead to catastrophic outcomes.

- In ecology, not understanding the dynamics of a fish population compounded with economic pressures (for employment preservation) can lead to extinction.
- In macroeconomics, low interest rates can lead to ``bubbles"; high interest rates to unemployment.
- The sustainable ``solution" to these problems is to find a way to avert catastrophe; i.e. maintain the system within the realms of safety or acceptability.

### Which questions can vt answer?

Viability theory (vt) has been explicitly developed to analyse invariant sets in which a dynamic system will remain, making it a perfect fit for considering problems of sustainability. In particular, vt can ascertain

- whether a system will be able to sustain itself according to the given sustainability criteria over some time-frame; and also
- Which system states afford the possibility of the system sustaining itself, and which do not.

Discussion Differential inclusions Kernel and policy Viabiltiy vs optimality

### Which questions can vt answer?

Viability theory *(vt)* has been explicitly developed to analyse invariant sets in which a dynamic system will remain, making it a perfect fit for considering problems of sustainability. In particular, *vt* can ascertain

### What is viable and what is not?

- If from a given system state there is an evolution which is feasible according to what is known about the system's dynamics and which sustains the system within the imposed bounds, then that system state is viable.
- Conversely, where there is no conceivable way for the system to remain within those bounds when starting from a given state, then this state is said to be non-viable.
- Identification of states as viable or non-viable is achieved in vt by computing the viability kernel V -- the largest closed subset of points in the constraint set for which all points are viable.
- In order for a system to be viable,  $\mathcal{V} \neq \emptyset$ .

### Is vt ``better" than optimal control?

- However, if agents are H. Simon's agents *i.e.*, believed to employ strategies that are ``good enough" in that they satisfy normative and modal (imposed by reality) constraints then vt is useful.
- In particular, vt introduces ``viable" control strategies, based around the concept of the viability kernel: unless the system is in danger of travelling from a viable to a non-viable state any (admissible) control will be viable.
- Under this view, vt provides (arguably) a better fit for the real concerns of regulators than optimal control does (constraints may be more ``objective" than a loss function, potentially complicated).

Discussion Differential inclusions Kernel and policy Viabiltiy vs optimality

### Behaviourists' delight?

In essence,

- vt has the potential to respond to the behaviourists' challenges and to provide insights into compatibility between the system's dynamics and the constraints' geometry;
- *vt* is an appropriate analytical tool for the analysis of sustainability problems which can be solved if the above compatibility has been understood.

In this presentation, *vt* will be used to solve the twin ecological-economic problem of sustaining fish population at a safe level whilst at the same time maintaining the profitability of fishing operations that impact that population.

#### Viable points

Given a differential inclusion *F* over some set *X*,  $x_0 \in K \subset X$  is viable in *K* under *F* if, starting from  $x(0) = x_0 \exists x(\cdot) : \Theta \mapsto X$ 

$$\forall t \in \Theta \left\{ \begin{array}{l} \mathbf{x}(t) \in \mathbf{K}, \\ \dot{\mathbf{x}}(t) \in \mathbf{F}(\mathbf{x}(t)), \quad \forall t \in \Theta \equiv [0, \infty) , \end{array} \right.$$

#### K is the constraint set imposed on the system evolving under F.

The above formulation has a philosophical interpretation: an evolution that starts at a viable point follows a path that satisfies fate F and desire K (``kraving"?).

• To go from one-state viability to area viability, we use the viability theorem.

Discussion Differential inclusions Kernel and policy Viabiltiy vs optimality

### Viable points

Given a differential inclusion *F* over some set *X*,  $x_0 \in K \subset X$  is viable in *K* under *F* if, starting from  $x(0) = x_0 \exists x(\cdot) : \Theta \mapsto X$ 

$$\forall t \in \Theta \left\{ \begin{array}{ll} \mathbf{x}(t) \in \mathbf{K}, \\ \dot{\mathbf{x}}(t) \in \mathbf{F}(\mathbf{x}(t)), \quad \forall t \in \Theta \equiv [0, \infty) \,, \end{array} \right.$$

*K* is the constraint set imposed on the system evolving under *F*. The above formulation has a philosophical interpretation: an evolution that starts at a viable point follows a path that satisfies fate *F* and desire *K* (``kraving"?).

• To go from one-state viability to area viability, we use the viability theorem.

#### Concluding remarks ar Viable areas

#### Theorem

D

Assume D is a closed set in  $\mathbb{R}^n$ . Suppose that the set valued map  $F : \mathbb{R}^n \rightsquigarrow \mathbb{R}^n$  is Lipschitz continuous with convex, compact, nonempty values. Then the two assertions are equivalent :

Differential inclusions

Viabiltiv vs optimality

Kernel and policy

**(a)**  $\forall x_0 \in D$ , there exists a solution  $x(\cdot) : \Theta \mapsto \mathbb{R}^n$  of

$$\begin{cases} \dot{\mathbf{x}}(\mathbf{s}) = F(\mathbf{x}(\mathbf{s})) \text{ for almost every } \mathbf{s} \\ \mathbf{x}(0) = \mathbf{x}_0 \end{cases}$$

which remains in D;

$$\forall x \in D, \quad \forall p \in \mathcal{NP}_D(x), \quad \min_{v \in F(x)} \langle v, p \rangle \le 0.$$

Discussion Differential inclusions Kernel and policy Viabiltiy vs optimality

- Problems modelled using a viability approach do not need to determine utility or loss functions in order to formulate policy rules, and therefore there is no need to calibrate such functions, hence no subjective appraisal of which constraints are more important is needed.
- Determining the bounds of the set *K* is a potentially much simpler task, given that such bounds (normative or modal) are often trivially observable.
- This contrasts with the optimisation approach where the constraints that define *K* are usually implicit in the loss function.
- The solution to *vt* problem's solution explicitly defines the set of acceptable states in *K*.

# Viability generalises stability

- The kernel is a closed set and it can be characterised by some measure, which the distance between two states in the kernel will never exceed.
- Knowing V<sub>F</sub>(K), makes the regulator aware of the locus of states in which the dynamic system can continue to exist, for a given ``strength" of implementable controls.
- If the system is in V<sub>F</sub>(K) (``stable") and when more than one control is viable, the regulator may strive to achieve other goals (e.g., political or ``wants" rather than ``needs").

# Algorithms

- An analytical characterisation of the viability kernel is rarely possible and most models using vt rely on numerical methods to compute their viability kernels.
- Classical algorithms were proposed by Frankowska, Quincampoix and Saint-Pierre. They work by ``whittling away" points that exit the set after one discrete-time step. Chapel and Deffuant have implemented Saint-Pierre's algorithm in a software package Kaviar.
- We propose two simple algorithms:
  - inclusion algorithm where points are included in D if there are controls that slow the system to an approximate steady state, and
  - eigentiation algorithm that is based on a paper by Gaitsgory & Quincampoix where the non-viable points can be characterised by a large value function.

Concluding remarks and future research

## **One-species fishery**

One-species fishery A by-catch fishery problem (one fleet, two fleets, policy advice Robustness of model

Viability has proven popular with ecologists seeking to model resource use. Béné et al have solved the following problem:

- Profits are given by R(x(t), e(t)) = pq<sub>x</sub>e(t)x(t) ce(t) C,
  p price, q<sub>x</sub>e(t)x(t) is the catch size, ce(t), C variable and fixed costs, respectively.
- $K = \{(x, e) : x \ge x_{\min} \land pq_xeb ce C \ge 0 \land e \in [0, e_{\max}]\};$ harvest rate  $h_x(t) = q_xe(t)x(t).$
- $\dot{\mathbf{x}}(t) = r\mathbf{x}(t) \left(1 \frac{\mathbf{x}(t)}{L_x}\right) q_x \mathbf{e}(t)\mathbf{x}(t)$  $\dot{\mathbf{e}}(t) \in \mathbf{U} = [\mathbf{u}^-, \mathbf{u}^+].$

One-species fishery A by-catch fishery problem (one fleet, two fleets, policy advice Robustness of model

- Satisficing solutions are generically non-unique and hence amenable to managers' own prioritisation.
- If fleets obey the  $U = U_1 \times U_2$  choices and also respect the overall system's viability (i.e. the profitability of both fleets, and the non-extinction of both species), then the two-fleet case constitutes a constrained qualitative game between the fleets.
- Our viability kernel provides an overview for the space in which the game will be played.
- This could help solve an *entry* problem, in which the second fleet is considering joining the fishery.
- Our analysis can help a regulator deciding whether or not to issue a permit for the second fleet to operate on the fishery.

Robustness of model

One-species fishery A by-catch fishery problem (one fleet, two fleets, policy advice Robustness of model

- A viability model needs fewer subjectively assessed parameters than the corresponding optimisation model.
- In particular, no weights on a fleet's ``importance".
- Neither is the discount rate needed.
- The bounds of the constraint set are either legislated or identifiable in a fairly non-objectionable manner.
- Boundaries of the viability kernel may convey more information about the desired evolution of the economy than an ``optimal" solution.

One-species fishery A by-catch fishery problem (one fleet, two fleets, policy advice Robustness of model

イロト イ理ト イヨト イヨト

#### Robustness of model cont.

- A viability model is robust because it allows for the system's inertia.
- I.e., a viable policy avoids or steers the system away from areas of no return.
- So, viable policies are precautionary.

#### Robustness of model cont.

- A viability model is robust because it allows for the system's inertia.
- I.e., a viable policy avoids or steers the system away from areas of no return.
- So, viable policies are precautionary.

## Conclusions

- We have presented some basic notions of viability theory and shown how this theory can be useful for modeling and solution of sustainability problems.
- Attempts should be made to analyse sustainability problems (including disease management) from the viability-theory point of view. Given that these (ecologic-economic, health care, etc.) problems' models are essentially nonlinear, more research is needed on kernel existence for such models.
- Computational algorithms that lead to kernel determination should be improved as they frequently suffer from the curse of dimensionality.
