The Hamiltonian Cycle Problem Polyhedral Domains for the HCP Two New Counterpart Problems for the HCP

# Complexity

Introduction NP Problems

#### Definition

The (worst-case) complexity of an algorithm is a measure of the amount of time and/or space required by an algorithm for an input of a given size.

• We say that the function f(x) is  $\mathcal{O}(g(x))$ , if and only if there exists a positive constant c and a real number  $x_0$  such that for all  $x \ge x_0$ ,  $f(x) \le c g(x)$ .

# Exploiting the Conjecture

### A New Algorithm for the HCP

- Construct the polytope  $WH_{\beta}$  corresponding to a given graph G, set  $\beta$  large enough and t = 1;
- Q Generate an extreme point of polytope WH<sub>β</sub>, say x<sub>t</sub>, uniformly, at random. If x<sub>t</sub> is a Hamiltonian extreme point, then STOP and claim that G is Hamiltonian;
- 3 If  $t > \alpha \rho(n)$ , then **STOP** and claim that with high probability, *G* is non-Hamiltonian. Otherwise, set t = t + 1 and return to Step 2.
  - For a given Hamiltonian graph G,

 $\Pr(\text{Required number of iterations} > \tau) \leq e^{-\frac{\tau}{\rho(n)}};$ 

• For a given graph *G*, we can solve the HCP, with high probability, in polynomial time.

 $egin{array}{c} \mathcal{H}_eta \ ext{and} \ \mathbf{g}(\mathsf{x};eta) \ \leq \ \mathbf{c}(eta) \end{array}$ 

#### Theorem (Borkar and Filar 2013)

Consider the graph G and construct the corresponding polytope  $\mathcal{H}_{\beta}$  and the convex body  $\mathcal{CH}_{\beta}$ . The graph G is **non-Hamiltonian**, if and only if  $\mathcal{H}_{\beta} = \mathcal{CH}_{\beta}$ . Otherwise, that is if G is **Hamiltonian**,  $\mathcal{CH}_{\beta} \subset \mathcal{H}_{\beta}$ .
