

# A REMARK ON A PAPER OF MINE ON POLYNOMIALS

BY  
 KURT MAHLER

1. The measure  $M(f)$  of a polynomial

$$f(x) = a_0 x^m + a_1 x^{m-1} + \cdots + a_m$$

with real or complex coefficients is defined by

$$M(f) = \exp \left\{ \int_0^1 \log |f(e^{2\pi it})| dt \right\} \quad \text{if } f(x) \not\equiv 0,$$

$$= 0 \quad \text{if } f(x) \equiv 0.$$

Denote by  $S_{mn}$  the set of all polynomial vectors

$$\mathbf{f}(x) = (f_1(x), \cdots, f_n(x))$$

with components  $f_h(x)$  that are polynomials at most of degree  $m$  and that do not all vanish identically. Further put

$$M(\mathbf{f}) = \sum_{h=1}^n M(f_h), \quad N(\mathbf{f}) = \sum_{h=1}^n \sum_{k=1}^n M(f_h - f_k),$$

$$Q(\mathbf{f}) = N(\mathbf{f})/M(\mathbf{f}).$$

In my paper *On Two Extremum Properties of Polynomials*<sup>1</sup> I proved that the least upper bound

$$C_{mn} = \sup_{\mathbf{f} \in S_{mn}} Q(\mathbf{f})$$

satisfies the nearly trivial inequality

$$(1) \quad C_{mn} \leq 2^{m+1}(n-1)$$

and is attained for a polynomial vector

$$\mathbf{F}(x) = (F_1(x), \cdots, F_n(x))$$

in  $S_{mn}$  with the following properties:

(2) *Those components  $F_h(x)$  of  $\mathbf{F}(x)$  that do not vanish identically all have the exact degree  $m$ , and all their zeros lie on the unit circle.*

It does not seem to be easy to determine the exact value of  $C_{mn}$ . In this note I shall replace (1) by an inequality (9) which is slightly better when  $m$  is large relative to  $\log n$ .

2. Let  $\mathbf{F}(x)$  be defined as before. Without loss of generality,

$$F_1(x) \not\equiv 0, \quad \cdots, \quad F_p(x) \not\equiv 0, \quad F_{p+1}(x) \equiv \cdots \equiv F_n(x) \equiv 0,$$

Received October 7, 1963.

where  $p$  is a certain integer satisfying

$$1 \leq p \leq n.$$

By (2), each of the first  $p$  components of  $\mathbf{F}(x)$  allows a factorisation

$$F_h(x) = c_h(x - \gamma_{h1}) \cdots (x - \gamma_{hm}),$$

where

$$c_h \neq 0, \quad |\gamma_{h1}| = \cdots = |\gamma_{hm}| = 1.$$

Therefore

$$M(F_h) = |c_h| \prod_{l=1}^m \max(1, |\gamma_{hl}|) = |c_h| \quad (h = 1, 2, \dots, p),$$

and it follows, in particular, that

$$(3) \quad M(\mathbf{F}) = \sum_{h=1}^p |c_h|.$$

The problem is to obtain an upper estimate for

$$N(\mathbf{F}) = \sum_{h=1}^n \sum_{k=1}^n M(F_h - F_k) = 2 \sum_{1 \leq h < k \leq n} M(F_h - F_k).$$

Here, from the hypothesis,

$$\begin{aligned} M(F_h - F_k) &= |c_h| \quad \text{if} \quad 1 \leq h \leq p, \quad p+1 \leq k \leq n, \\ &= 0 \quad \text{if} \quad p+1 \leq h \leq n, \quad p+1 \leq k \leq n. \end{aligned}$$

Thus it suffices to estimate the remaining terms

$$M(F_h - F_k) \quad (1 \leq h \leq p, \quad 1 \leq k \leq p)$$

of  $N(\mathbf{F})$ .

3. As usual, put for positive  $s$

$$\log^+ s = \max(0, \log s),$$

so that

$$(4) \quad \begin{aligned} \log s &\leq \log^+ s; \quad \log^+(st) \leq \log^+ s + \log^+ t; \\ \log^+ |s \mp t| &\leq \log^+ s + \log^+ t + \log 2. \end{aligned}$$

If further  $f(x)$  is again any polynomial, put

$$\begin{aligned} M^+(f) &= \exp \left\{ \int_0^1 \log^+ |f(e^{2\pi it})| dt \right\} \quad \text{if} \quad f(x) \neq 0, \\ &= 0 \quad \text{if} \quad f(x) \equiv 0. \end{aligned}$$

Then, by (4),  $M^+(f)$  has the properties:

$$(5) \quad \begin{aligned} M(f) &\leq M^+(f), \\ M^+(fg) &\leq M^+(f)M^+(g), \\ M^+(f \mp g) &\leq 2M^+(f)M^+(g). \end{aligned}$$

If further  $a$  is any constant,

$$(6) \quad M^+(a) = \max(1, |a|).$$

4. From these formulae (5) and (6),

$$M(F_h - F_k) \leq M^+(F_h - F_k) \leq 2M^+(F_h)M^+(F_k),$$

where, e.g.

$$M^+(F_h) \leq \max(1, |c_h|) \prod_{l=1}^m M^+(x - \gamma_{hl}).$$

Moreover,

$$M^+(x - \gamma_{hl}) = M^+(x - 1)$$

because  $\gamma_{hl}$  has the absolute value 1.

For shortness therefore put

$$\theta = M^+(x - 1) = \exp \left\{ \int_0^1 \log^+ |e^{2\pi it} - 1| dt \right\}.$$

It follows then that

$$M^+(F_h) \leq \max(1, |c_h|)\theta^m,$$

whence, for  $1 \leq h \leq p, \quad 1 \leq k \leq p,$

$$(7) \quad M(F_h - F_k) \leq M^+(F_h - F_k) \leq 2 \max(1, |c_h|) \max(1, |c_k|)\theta^{2m}.$$

Now, for any constant  $a \neq 0,$

$$Q(a\mathbf{f}) = Q(\mathbf{f}).$$

Thus there is no loss of generality in assuming that

$$M(\mathbf{F}) = \sum_{h=1}^p |c_h| = 1,$$

and hence that

$$\max(1, |c_h|) = 1 \quad (h = 1, 2, \dots, p).$$

The estimate (7) takes then the simpler form

$$M(F_h - F_k) \leq 2\theta^{2m} \quad (1 \leq h \leq p, \quad 1 \leq k \leq p),$$

and it follows that

$$\sum_{h=1}^p \sum_{k=1}^p M(F_h - F_k) \leq 2(p^2 - p)\theta^{2m}$$

because the  $p$  terms with  $h = k$  vanish. Therefore, by

$$N(\mathbf{F}) = \sum_{h=1}^p \sum_{k=1}^p M(F_h - F_k) + 2(n - p) \sum_{h=1}^p M(F_h),$$

we obtain the inequality

$$(8) \quad Q(\mathbf{F}) = N(\mathbf{F}) \leq 2(p^2 - p)\theta^{2m} + 2(n - p).$$

5. An approximate value of  $\theta$  is now easily obtained. Write

$$j = \log \theta = \int_0^1 \log^+ |e^{2\pi it} - 1| dt = \int_{-1/2}^{1/2} \log^+ |e^{2\pi it} - 1| dt.$$

The function

$$|e^{2\pi it} - 1| = 2 |(e^{\pi it} - e^{-\pi it})/2i| = 2 |\sin \pi t|$$

is even and of period 1, and

$$\begin{aligned} |e^{2\pi it} - 1| &\leq 1 && \text{if } 0 \leq t \leq \frac{1}{6}, \\ &> 1 && \text{if } \frac{1}{6} < t \leq \frac{1}{2}. \end{aligned}$$

It follows that

$$j = 2 \int_{1/6}^{1/2} \log (2 \sin \pi t) dt = \frac{1}{3} \log 4 + 2 \int_{1/6}^{1/2} \log \sin \pi t dt.$$

Here, by numerical integration (for which I am much indebted to my colleague Professor K. J. Le Couteur),

$$\int_{1/6}^{1/2} \log \sin \pi t dt = -0.069516 \dots,$$

and hence

$$j = 0.32307 \dots.$$

Therefore

$$\theta^2 = e^{2j} < 1.91.$$

Since  $p \leq n$ , it follows then finally from (8) that

$$Q(\mathbf{F}) \leq 2(n^2 - n)\theta^{2m} + 2(n - n),$$

and therefore that

$$(9) \quad C_{mn} \leq 2(n^2 - n)\lambda^m \quad \text{where } \lambda < 1.91.$$

Apart from the value of the constant  $\lambda$ , this result is best possible for fixed  $n$  and increasing  $m$ . This is easily seen for  $n = 2$  on taking for  $\mathbf{f}(x)$  the polynomial vector

$$\mathbf{f}(n) = ((x + 1)^m, (x - 1)^m).$$
